

Using Quasi-static Magnetic Fields and Meta-material Amplifiers to allow for Ubiquitous Wireless Charging

Jordan Hill

November 7, 2018

Abstract

Quasi-static Magnetic fields are Electromagnetic fields that are designed that have current direction, α , pass through a series of discrete capacitors, known as μ_x , and so on depending on the number of capacitors being used to generate the Quasi-static Magnetic Field. This, combined with the use of Meta-materials, that have the ability to allow for high amounts of electric resonance, have the possibility to allow for highly efficient wireless charging, and solve the problem of current wireless charging, and it being restricted to the device always being stuck to a pad while charging, and not allowing the user the use of mobility while using wireless charging with modern methods. My Hypothesis

1 Introduction

Wireless Charging, the Pinnacle of refueling devices, free of constraints, nothing holding the user back from being forced to charge with the length of cord limiting there freedom to move around while charging there device. But, a problem is present with Modern Wireless Charging in the current form that it is used in currently, and that is the need for a connection constantly to charge your device. The current method of wireless charging used today is known as Qi Charging. Qi Charging works with the wireless charging device having a built in copper coil. The Copper Coil is attached to the battery of the device, so current is put into the battery correctly while the device is charging. Power is transferred to the device through a Wireless Charging Pad, containing a Copper Coil inside the Pad. Transfer of Power is done between these two coils, using the coil inside the device as an inducting coil, and an alternating electromagnetic field is created. This field is the process responsible for allowing the wireless charging to occur in Qi Charging, and charge the device in Question. But, there is a problem with this process, and that is the lack of mobility, as when you place the device on the pad, you cannot under any circumstances remove it, as if you remove it from the pad, you lose the electromagnetic field that was made between the two coils, one in the pad and the device itself, which stops the charging process itself, which shows the Problem of Mobility with this method of wireless charging comes into play. Now, the answer to this problem is quite simple, and that is with the use of a Material, a Special material, and the types of that being referred to as Meta-materials. Meta-materials are special materials, designed to have properties not found in any other modern material that would be found in Nature, and have a variety of properties when produced. Some of these materials have been known to have the ability to reflect electromagnetic waves, and reflect them completely, having no interaction with the Material itself what so ever. This application of such Meta-materials has great application to solve the problem of mobility with wireless charging. Meta-materials can contain these properties, mainly due to the construction of there unit cells, which make up the fundamental structure of the material itself, and its properties, such as impedance within the material. Impedance is the electrical resistance within the component of an alternating current and the electrical resistance within that component.

2 Background Research

Background Research of this project mainly surrounded

3 Mathematical Modeling

Mathematical Modeling used within this project worked with many equations, but one of the main ones being for the

4 Design of Meta-material Unit Cell

When designing the Meta-material Unit Cell, multiple factors were taken into account for the design, that being the greatest amount of resonance that would have to be achieved.

5 COSMOL Simulations

For the simulations for this project within COSMOL, that being the version of COSMOL being 5.2A

6 Data Collection

Collection of data was done mainly with the harvesting of data from COSMOL, and
